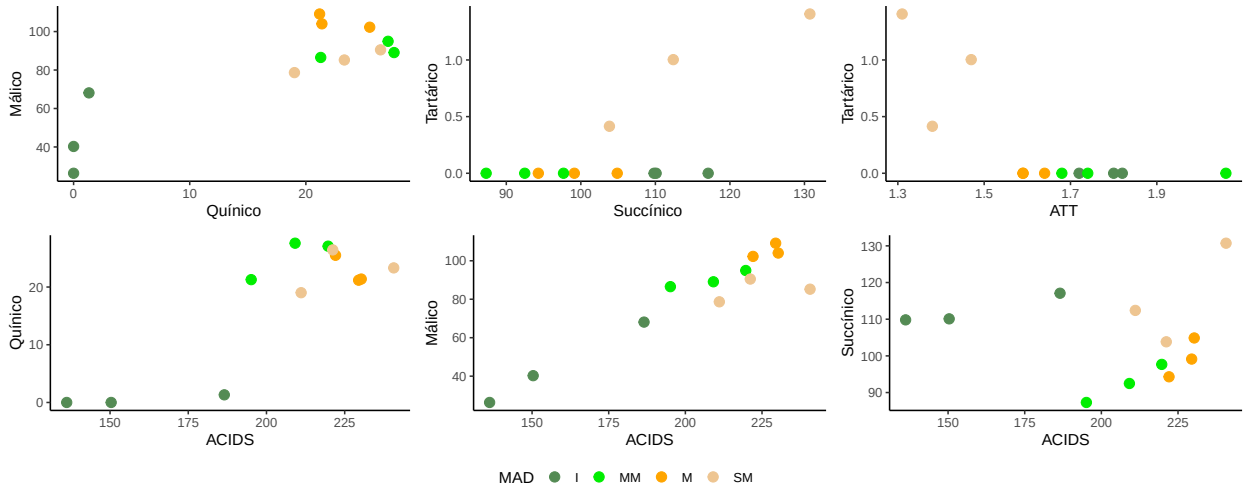
Gráficos de correlación detallados por estado.



- Correlaciones: Se evidenciaron relaciones lineales entre los ácidos orgánicos, entre el ácido málico y el ácido quínico con un coeficiente de correlación (r) de 0.8600213 y un valor de p=0.000333, y entre el ácido tartárico y el ácido succínico con un r=0.6869819 y un p-valor=0.01358. La acidez titulable total (TTA) mostró una asociación lineal significativa únicamente con el ácido tartárico, con un r=-0.7187027 y un p-valor=0.00845. Sin embargo, esta asociación inversa está vinculada al hecho de que el ácido tartárico solo aparece en cantidades mínimas en frutas muy maduras. La concentración total de ácidos con ácido quínico presentó una correlación de 0.8557676 con un p-valor=0.0003839. Mientras tanto, el ácido málico mostró un r=0.9300893 y un p-valor=1.169e-05. En ambos casos, estos ácidos explican el aumento en la concentración total de ácidos a lo largo del proceso de maduración de la fruta.
